Project Advisor

Abstract

CoViD-19 has killed millions of people around the world over the past eighteen months, making research mandatory. This includes its diverse effects upon various groups.

Statistical analysis included the use of a BRN formula and a percentage breakdown of population versus cases. In doing so, communities with epidemic spread of CoViD-19 could be identified, as well as the hardest-hit groups.

Well-off communities had significantly higher BRNs. However, cases occurred in disproportionate amounts in the communities with the lowest infection rates.

Acknowledgment

This project would not have been possible without the help and support of innumerable people. Special credit must be given to the following:

My family: my mother, father, sister, and grandmother all listened to my complaints, and to my celebrations. They provided a sounding board for my work and they are the people I look forward most to sharing this paper with.

My friends, especially Ari, Dakota, Ginger, and Gwendalyn. Their support as I worked on this paper, their time when I needed to talk to someone, and their understanding when this work took priority over plans all deserve more thanks than I can give.

My professors, who provided me with the expertise needed to produce this paper. Special credit must be given to Professor Arnold and Professor Lui. Professor Arnold deserves credit for stoking my love of mathematics, and Professor Lui for igniting an interest in the study of CoViD-19. Many of the concepts explored in this paper are the direct result of the time that Professor Lui took to explain epidemiology, and due recognition must be given to his efforts.

My peers, especially Alex and Javier. Without their collaboration on Modeling CoViD-19 in Massachusetts, Texas and Iowa, my understanding of the next-generation method to determine the Basic Reproduction Number and of parameter tuning would be sorely lacking.

Finally, Professors Fofana and Krueger. Their work to guarantee that this project was a success cannot be understated, and I am infinitely grateful for the faith put in me and my abilities.

I hope to have made everyone – my family, friends, professors, peers, and advisors – proud.

1 Threats from Infections and Emerging Infectious Diseases

CoViD-19 is a deadly disease that has already killed 600,000 people in the United States alone, with hundreds of other deaths around the world. It has infected 38.5 million people in the United States, and continues to spread. Without meaningful examination of the spread of CoViD-19, with close examination of the communities most at risk, the virus will continue to infect, to spread, and to kill. With such knowledge, more resources and investment can be given to the groups and areas most at risk.

To this directive, studies can be conducted which compile, process, clean, and analyze the data made available by the state of Massachusetts. Such is the purpose of this study. By documenting the groups of society most in need of aid during the current pandemic, and by providing additional medical focus, such as increased programs about the effectiveness of masks, increased regulation of CoViD-19 restrictions, and increased efforts to provide vaccines to the communities, their risk might approach the norm. Of course, repeating this study to determine if the rate of infection has decreased will be invaluable to

determining the efficacy of such efforts. Any future studies can also identify the communities that are most at risk once the spread has been appropriately curbed in the first identified communities. If such efforts prove worthwhile, this method can be generalized to other states and nations. In doing so, the spread of CoViD-19 may leave its current epidemic state, and may become endemic.

If this research proves to be this impactful, then it may also be used to map future pandemics, and identify the communities most affected by a different virus. In this situation, the focus can first be on the communities identified as at-risk in this study, and then as more data is analyzed, a more specific response can be formulated and executed. This data can also be used to coordinate general medical practice. When communities are identified as at-risk during a pandemic, they likely are at risk in general. Thus, this data holds value outside of the current CoViD-19 crisis, both as a roadmap for future epidemics, and as a reference for medical needs. In fact, this study's power for predicting medical need would be augmented by repeated research across other viruses - with more data across different periods and circumstances, a more detailed map of needs can be made.

In order to complete a study such as this, there are some requisite steps that must be followed. First, data must be found, which provides the infections at a time interval approximately equal to the length of a period of infection - in this case, the data used was biweekly.

From here, the population can be split into the documented groups, such as Lifestyle Social Contract (LS2C), Infected, and Uninfected. If the data allows, additional categories such as Deceased, Hospitalized, and Exposed can be added to the list of classes. From here, a mathematical model must be devised, which provides a system of equations that maps the movement of peoples through the various classes. After proving the validity of such a system, it can be used to calculate the Basic Reproduction Number (BRN) for the data. Bar graphs can also be made, which compare a group's percentage of the population to their total percentage of cases.

At this point, tables must be constructed, dividing the population into its subordinate groups being analyzed, and then documenting the state of each population in relation to the mathematical model. From this information, the Basic Reproduction Number formula may be executed, so as to remove population weighting and create comparable data.

If desired, the data for all groups may be evaluated on a singular date, or the data for all dates may be evaluated for a singular group. From these tables, comparisons can be made as to the spread of a given virus over a period of time between communities for each viral reproduction period. This data can be consolidated to any multiple period, by adding weeks of appropriate data together and recalculating. Monthly and seasonal periods were chosen for this study. After this, at-risk communities can be identified and additional aid can be provided.

This paper is organized as follows:

2 Landscape of Coronavirus and Efforts to Stop the

Virus Spread

CoViD-19 is a novel coronavirus disease, which was first discovered on December 31st of 2019¹. This is the basis for its name – Co(rona)Vi(rus)D(isease)–(discovered 20)19¹.

Coronaviruses are a form of viral disease, which are so named due to their spiky appearance, like a crown – in latin, *corona*¹. Coronaviruses come in four main types:

2

Common coronaviruses include:

2

These are all common colds².

Other well-known coronaviruses are MERS-CoV – also known as Middle East Respiratory Syndrome Coronavirus, and SARS-CoV – or Severe Acute Respiratory Syndrome Coronavirus³.

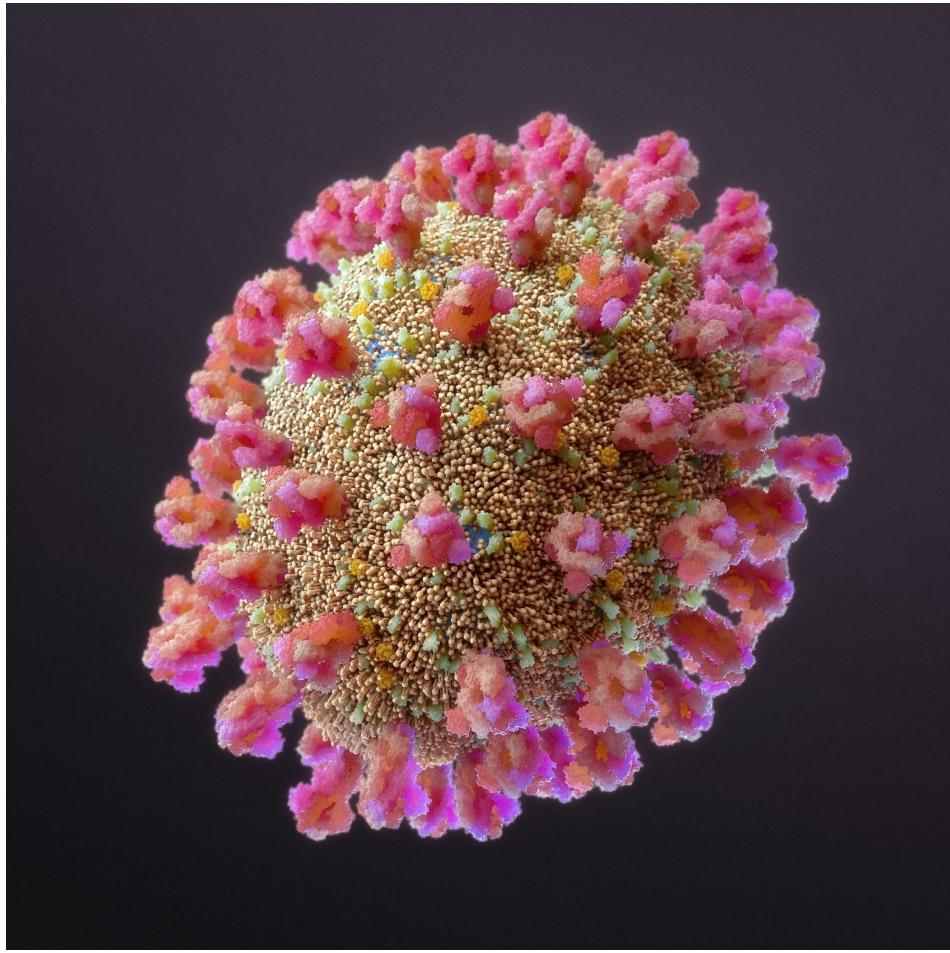

CoViD-19 has been such a concerning virus because of its myriad symptoms. These range from the “mild case” symptoms of:

4

Hospitalized cases may include the following:

4

CoViD-19 was originally discovered in the Wuhan province of China⁵. This acted as an epicenter for the virus, and many of the original studies were focused on this region⁵. As the virus spread, the focus of studies expanded to include the other infected locations.

A CoViD-19 Molecule

By the end of January, this included the United States, as the first case was reported in Washington state⁵. By the end of the month, then-President Trump had declared a Public Health Emergency, restricting travel from China⁶. Besides this, little action was taken until March, at which point, many states mandated masks, limited gatherings, closed schools, and eliminated non-essential travel⁷. By April, all states had reported cases of the virus⁸. Due to economic pressures, some restrictions were periodically lifted, but these frequently resulted in an increase in cases and the subsequent reinstatement of those restrictions.

One of the most notable early studies is that of Tang et al., who used Markov Chain Monte Carlo simulations to determine the parameters of a nine-class expanded SIR model, using data from Wuhan⁹. Such studies provide important data on the spread of CoViD-19. However, there are still questions that remain on the topic. Further analysis of data, especially localized data from an extended period, has value in improving understanding of the transmission of the virus.

These data localization points can be as large as a continent, or as small as a town. They can be devoid of location entirely, and instead focus on age, gender, or race. All of these provides valuable insight into the communities most at risk for the virus.

Fortunately for those studying CoViD-19, there is a plethora of information. 220 countries and

territories have reported data on CoViD-19¹⁰. Some nations, such as the United States, have provided regional information, or data on the ethnicity, sex, and age of CoViD-19 cases.

It has already been noted by many scholars that the virus has been disproportionately affecting minority communities¹¹. Black, Hispanic, and Native American communities each have a greater percentage of cases and deaths than they do percentage of the population¹¹. Similar data is difficult to find for gender and age; however, it is commonly noted that the changes in lifestyle associated with aging typically result in an increased risk of death for CoViD-19 patients, and that nursing homes are responsible for the spread of CoViD-19, although this information is more anecdotal and less data-driven^{12,13}.

This data frequently includes the number of deaths attributed to CoViD-19. With the latest data suggesting over 3.85 million cases, 616,358 of which occurred in the United States, it is evident that the virus requires close examination in order to help determine who is the most at-risk, which can reduce mortality¹⁰.

This urgency is especially relevant with the advent of CoViD-19 vaccines. These inoculations from Moderna, Pfizer, and Johnson & Johnson help reduce the spread of the virus, and have been heavily encouraged for everyone age 12 and up¹⁴. It is important to identify the groups and communities most in need of the vaccine, because more resources can then be invested in such areas.

CoViD-19 is a phenomenon with substantial information, and misinformation, available. This project cannot substantially alter the depth of misinformation around the virus; however, it can provide more accurate and more advanced data on subsets of interest – namely, the communities and peoples most at risk for the Novel Coronavirus.

3 Epidemiology

A way to study the spread of CoViD-19 is through the use of epidemiology. By studying specified groups and their distribution of CoViD-19 infection and recovery, researchers develop insight into the causes and risk factors for the virus's spread¹⁵. Such research can be based on distinguishing characteristics such as age, gender, race, county, educational status, and hundreds of other divisions¹⁵. These allow researchers to determine if commonalities can be found in groups that are infected at greater rates, and in groups that are infected at lower rates, than the norm¹⁵.

Epidemiology has several elements: it is a part of determining all of the variations in severity of a disease, of determining transmission rates and risks, determining the risk factors for death or life-changing illness, and developing responses to a disease¹⁶. This study focuses on the transmission rates and risks, but it is important to note the work done in the other categories.

Firstly, credit must be given to Dr. Fauci and the Center for Disease Control (CDC), who have held press briefings and shared information throughout the pandemic¹⁷. These have provided invaluable recommendations, which helped reduce the spread of the virus. Advice such as mask mandates, social distancing of at least six feet, lockdown, eliminating pleasure travel, and regular CoViD-19 tests all helped to bring the rate of infection down to less than half of the Basic Reproduction Number (BRN) of the virus¹⁷.

Dr. Fauci Gives a Speech on CoViD-19

This necessitates the recognition of teams of researchers, such as Tang et al., who helped document the BRN while accounting for quarantining⁹. By examining the many different severities of CoViD-19, and creating a mathematical model accounting for each class of the population in a quarantine state, an understanding of the severity of the virus was reached before the number of cases snowballed⁹.

The researchers of CoViD-19 worked closely with the World Health Organization (WHO), whose authority helped extend the impact of research and provided invaluable global data on CoViD-19. In doing so, comparisons between response methods could be more easily made, increasing the rate of research.

Of course, CDC recommendations and research would not have halted the virus alone - Governor Charlie Baker deserves accolades for his hard-line stance against CoViD-19, informed by Dr. Fauci, research teams, and WHO. His efforts to eliminate all unnecessary travel, to mandate quarantine, and to place a capacity limit on events all reduced the spread of the virus¹⁸.

Governor Baker Announces CoViD-19 Restrictions

All of this work makes it possible for CoViD-19 to have less of an impact in the future. CDC teams can execute Field Epidemiology Training Programs (FETP) with the information on CoViD-19, to help prevent future outbreaks¹⁹. These programs help by deploying teams to viral areas, where they track the spread and provide education on controlling a disease¹⁹. According to their mission statement, with this work, they can begin to develop national, regional, and local capabilities to eliminate disease outbreaks before they begin²⁰.

A Field Epidemiology Training Program Ambulance (Side)

A Field Epidemiology Training Program Ambulance (Inside)

A Field Epidemiology Training Program Ambulance (Front)

It also allows more specialized care in hospitals and when emergency medical services are required²¹. With more data on at-risk communities, and an understanding of the various severities of a virus, medical aid can be provided quicker and more accurately²². With more knowledge on a disease, a response to cases can be tailored to the characteristics of the case and of the individual, increasing the likelihood of survival and decreasing the risk of infecting others²².

Of course, this relies on an understanding of CoViD-19 and of the communities most at risk. This is most easily done through mathematical modeling, such as that done in this study.

4 Mathematical Modeling

To analyze the data, it is easiest to view as a simple *S/R* model. Although the data can be viewed without a model, this does not take into account the weights of the information. As such, a system of equations, weighted for the population, contributes more meaningful information.

The *S/R* model utilized is as follows:

	$\dot{S} = -\frac{\beta IS}{N}$	(1)
	$\dot{I} = \frac{\beta IS}{N} - \gamma I$	(2)
	$\dot{R} = \gamma I$	(3)

S represents the number of Susceptible people in a population, which are those who have never been infected or recovered. This group will be considered those with a Lifestyle-Social Contract, or LS2C. I represents the people who are currently Infected, and R is the removed people – those who have died, or recovered and have immunity. This study will ignore the vaccination as a method to create immunity, as there is not sufficient data on the subject.

Instead of using starting parameters, which would unfairly bias data, the values can be calculated on a biweekly basis. It cannot occur more frequently than this, as the average length of infection is approximately 10-14 days. To calculate weekly would be to re-count too high of a percentage of cases.

Basic lemmas must be proven in order to have confidence in the model used. Although the proofs for a basic SIR model are well-known, verification is a necessary step of the process. As such, the population's constancy; the steady states; and, the basic reproduction number, must all be shown.

Lemma 1

Let

$$N := S + I + R. \quad (4)$$

Then

$$\dot{N} = 0. \quad (5)$$

This implies that

$$N(t) = N_0 := N(0) \quad (6)$$

for

$$t > 0. \quad (7)$$

This means the population size remains unchanged for all time.

Proof

Because (4),

$$\dot{N} := \dot{S} + \dot{I} + \dot{R}. \quad (8)$$

By (1), (2), and (3),

$$\dot{N} := -\frac{\beta IS}{N} + \frac{\beta IS}{N} - \gamma I + \gamma I. \quad (9)$$

This clearly means that

$$\dot{N} := 0. \quad (10)$$

The proof of the lemma is complete.

Lemma 2

The only steady-state of the model is

$$(S, 0, R) \quad (11)$$

where

$$S + R = N_0 .$$

(12)

Thus, in the long run, part of the susceptible population remains uninfected (susceptible), while the rest of the population become infected and at the end either recovered or died.

Proof

I can be factored out of (1), (2), and (3), resulting in

$$\dot{S} = I \left(-\frac{\beta S}{N} \right)$$

(13)

$$\dot{I} = I \left(\frac{\beta S}{N} - \gamma \right)$$

(14)

$$\dot{R} = I(\gamma)$$

(15)

Thus, if,

$$I = 0,$$

(16)

$$\dot{S} = \dot{I} = \dot{R} = 0.$$

(17)

The proof of the lemma is complete.

Lemma 3

The basic reproduction number, R_0 , of this model is given by

$$R_0 = \frac{\beta S}{N\gamma} .$$

(18)

Proof

The Next-Generation Method can be used to determine R_0 . Doing so requires a matrix of methods in which a Susceptible individual may become Infected (matrix \mathcal{F}), and a matrix of methods in which an Infected individual may become Removed (matrix \mathcal{V}). For an SIR model, this is easy:

$$\mathcal{F} = \frac{\beta IS}{N},$$

(19)

and

$$\mathcal{V} = \gamma I$$

(20)

R_0 is \mathcal{K} , where

$$\mathcal{K} = \mathcal{F}\mathcal{V}^{-1} .$$

(21)

Thus,

$$\mathcal{K} = \frac{\beta IS}{N\gamma I} = \frac{\beta S}{N\gamma} .$$

(22)

The proof of the lemma is complete.

5 Cleaning and Processing

The data chosen for analysis fits in to five categories:

Massachusetts has provided information on all five of these groups²³.

The Massachusetts total data is also available on the table with county data. To determine the average incidence rate in Massachusetts, it will be used independently of any table, using 2019 population estimates from the 2010 census²⁴. This will show if any group is above or below the mean.

5.1 Age

Age has been divided into the groups:

This table provides a weekly update on the number of cases, and population estimate for each of the age groups. Although the weekly information is available, a biweekly chart is made. Using this information, the Uninfected can be found by adding the previous period's Infected to the last period's Uninfected. Then, the Lifestyle-Social Contract can be determined by subtracting the current Infected and Uninfected from the population.

While this method works, it has its flaws. Since the data begins on August 12, 2020 (spanning back to July 26th), the 107,897 cases prior to July 26th are not counted. Thus, a method to distribute them fairly among each age group is needed. This can be done either by using a weighted average of the population estimates, or a weighted average of the cases at the end of data gathering on April 21st. The first ignores trends and creates its own, but the second reinforces the trends found at the end on the beginning cases. In order to maintain the same trends, the preexisting cases are divided using a weighted average of the cases at the end of April, with the acknowledgment of the biases created.

5.2 Gender

The second table, on gender, has four categories:

The same process is used to construct this table as was used for the first.

A notable difference, however, is in the calculation of the transgender cases. Since this data is not available before December 30th, a method to account for this must be used. Additionally, the population estimate for transgender people is not available; however, studies suggest that approximately 0.57% of the population of Massachusetts is transgender²⁵. This statistic can be used to calculate the total number of transgender peoples, and more accurately represent the population for females and males, by multiplying both groups by 0.0057 for the transgender population, and each by 0.9943 for their actual population. This ignores disparities between likelihood for males to be transgender vs females to be transgender, but it is better than the alternative of doing nothing.

This process can also be used to calculate transgender CoViD-19 cases before December 30th. These

numbers are substantially higher than those after December 30th, so both using this method and ignoring previous transgender cases will be used.

An additional note on this data is that some weeks have less than five cases for transgender people. This will be addressed by using the average.

5.3 Race

The Massachusetts data for race is presented differently than that of age or gender. Here, a cumulative total of cases can be found. This means that the information is for the total Uninfected in the next biweekly period. Thus, the current biweekly Lifestyle-Social Contract is the estimated population minus the cumulative cases, and the current Infected is the cumulative from the current week, with the last biweekly period's cumulative subtracted

This method, while more roundabout, does have its benefits: namely, it means that all cases are included in the cumulative data, and no biases will be presented by artificially adding them. This means that the data is more reliable.

There is, however, still an issue with the data: two categories:

Only begin reporting on December 30th. They cannot be properly estimated before then. The other six races:

All can be accurately tracked back to June 3rd.

June 3rd is not the first date of data, but it is the best starting date. From June 1st through November 1st, racial data was provided daily, but starting on November 4th, data is weekly. Therefore, the dates for biweekly data must line up with November 4th, which is why June 1st is used.

5.4 County

The fourth table is by county. Here, the case count is both cumulative and new. This means that the starting state is accessible, and after this, the methods used for Tables 1 and 2 can be used. The population for each county is not provided, but can be estimated using the 2010 Census data's estimate for 2019 population²⁶.

The counties are as follows:

It is worth noting that Dukes and Nantucket are separate counties; however, their data is only presented for both together. Thus, they will be analyzed as one entity.

5.5 Higher Education

One of the primary areas of concern for the pandemic has been school settings. The data on CoViD-19's spread is available for higher education, which will be analyzed to determine how much risk a college setting brings. There are no subcategories of this data, and it is of the same form as county data and will be treated in the same fashion. The table does not provide any information on the number of higher education students in Massachusetts, but this data can be easily found elsewhere²⁷.

5.6 Table Presentation

The data in these categories can be presented in various methods. A book can contain dated sheets, where the categories are all on one sheet. Alternatively, the sheets could each be a category, with all dates on one sheet. The first allows easy comparison between groups, while the second allows the SIR

model to be most easily used, providing the BRN for each period. Thus, both will be made.

The Excel formula for R_0 in a given row x is as follows:

For the first row:

$$\frac{(C(x+1) - C(x))B(x)}{(E(x+1) - E(x))C(x)} \quad (23)$$

For the second row to the second-to-last ($n - 1$) row:

$$\frac{(C(x+1) - C(x-1))B(x)}{(E(x+1) - E(x-1))C(x)} \quad (24)$$

For the last (n) row:

$$\frac{(C(x) - C(x-1))B(x)}{(E(x) - E(x-1))C(x)} \quad (25)$$

In addition to these separations, the length between dates can be changed to months or seasons. A month would be a period of two biweekly data sets, and a season would be a period of three monthly data sets. All three versions of dated sets allow for different analysis, and should all be made.

From this set of R_0 values, the mean can be calculated using the average function of Excel. Additionally, the Rank and Percentile Data Analysis tool of the Analysis ToolPak Add-in allows an easy determination of the time periods with a Basic Reproduction Number below the 25th percentile and above the 75th percentile.

External statistical analysis was used to determine the groups in each table below the 25th percentile and above the 75th percentile for the average BRN.

6 Tips for State of Readiness and Operational Effectiveness

The data gleaned from this study suggests the communities with the highest rate of infection, and ignores the severity of any given instance of CoViD-19. It is additionally of note that the order of impact changes with the period analyzed. This is likely due to the fact that if there was an uneven amount of biweekly periods, the final biweekly period was eliminated. Similarly, if the number of monthly periods was not a multiple of three, the final one or two was removed to create a factor of three number of periods.

The following table for Massachusetts will be used for comparison:

Massachusetts
Reference Average

R_0

Period	R_0
Biweekly	1.150
Monthly	1.368
Seasonal	4.598

It is important to note that the R_0 value increases as the period gets larger. This is the result of the formula for the first week, which becomes a much larger value than the other equations and artificially inflates the average. It does not decrease the validity of the data, but changes the comparison.

It is also of note that the actual Basic Reproduction Number is higher than those found. This represents the spread of CoViD-19 in a mask-mandated, socially distanced, and event-capacity-limited state, which all play a roll in reducing infection. If the virus spread freely, the BRN would likely be closer to 6, as suggested by Tang et al.

$\frac{B(x)}{\sum(B2:B(n))}$	(26)
------------------------------	-------------

The formula for the percentage breakdown of the population is above, and that for a percentage breakdown of the total cases is below. Note that any unknown or other groups are not accounted for in the percentage breakdown of cases, so the sum of percentages will be less than 100 for each set of data.

$\frac{D(x) + E(x)}{\sum(D2:E(n))}$	(27)
-------------------------------------	-------------

Where x represents the current row and n represents the last row in both equations.

Although graphs are provided for the biweekly, monthly, and seasonal periods, they are consistent to the point that only one must be analyzed. This suggests that the percentage ever infected does not change substantially throughout the time analyzed – the removal of the final weeks and months to make monthly and seasonal graphs does not have an impact on the model, so they must match the model.

6.1 Age

The data on age is represented in the following tables:

Biweekly Age
Average R_0

Rank	Age	R_0
1	0-19	1.207
2	20-29	1.190
3	30-39	1.189
4	40-49	1.186
5	50-59	1.183
6	60-69	1.173
7	70-79	1.134
8	80+	1.118

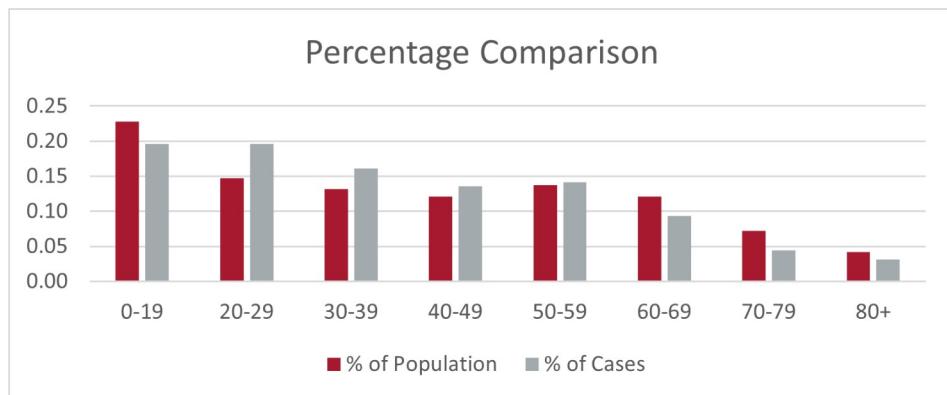

Monthly Age Average
 R_0

Rank	Age	R_0
1	0-19	1.459
1	20-29	1.459
3	60-69	1.453
4	50-59	1.448
5	40-49	1.432
6	30-39	1.426
7	70-79	1.372
8	80+	1.367

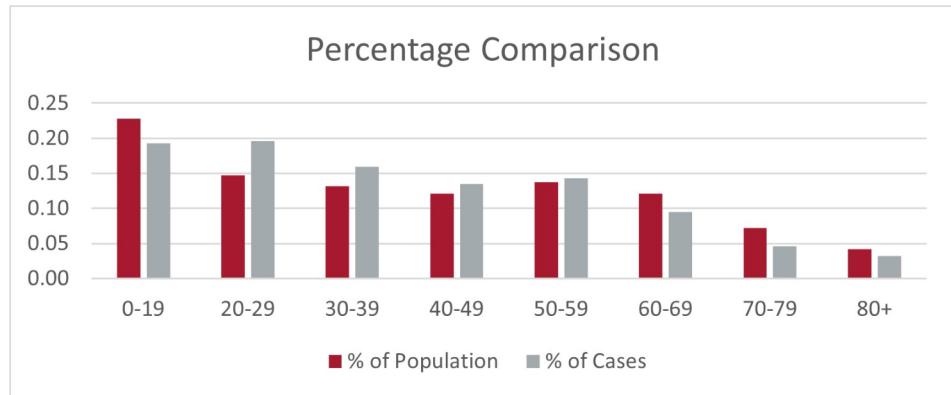

Seasonal Age Average
 R_0

Rank	Age	R_0
1	60-69	4.233
2	70-79	4.010
3	50-59	3.902
4	80+	3.878
5	40-49	3.520
6	0-19	3.482
7	30-39	3.376
8	20-29	3.280

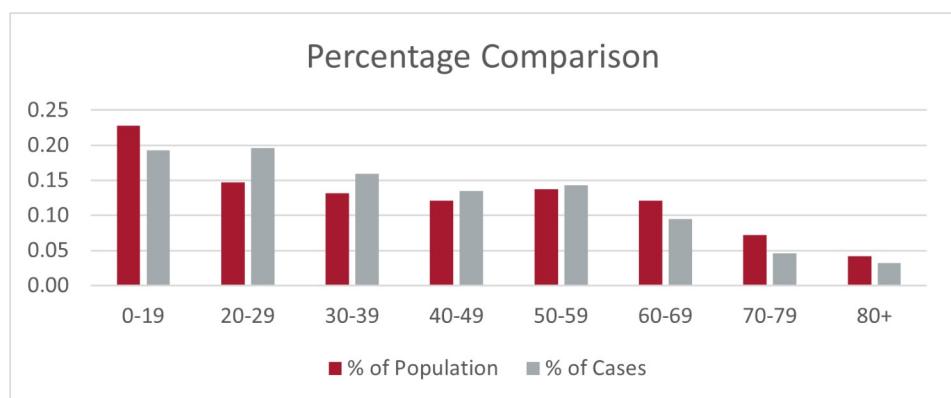

and the following charts:

Biweekly Age Percentage Comparison

Monthly Age Percentage Comparison

Seasonal Age Percentage Comparison

This data suggests that those aged 0-29 are the most likely to catch CoViD-19. Younger people put themselves in situations where they are more likely to be infected, while older individual have been reducing their risk of contamination.

The data on age suggests that the groups where recovery efforts should be focused are 20-49. These groups all have higher rates of infection than they should by population. This means that the age group of 20-29 deserves the most attention, as the most infected population with the second most rapid spread.

Thus, future campaigns for CoViD-19 safety should target younger crowds; however, this classification should be closely watched, as it seemseasibly susceptible to change.

6.2 Gender

The data on gender is represented in the following tables:

Biweekly Gender Average
 R_0 (Method 1)

Rank	Gender	R_0
1	Male	1.192
2	Female	1.176
3	Transgender	0.6982

Biweekly Gender Average R_0
(Method 2)

Rank	Gender	R_0
1	Male	1.192
2	Female	1.176
3	Transgender	1.107

Monthly Gender Average R_0
(Method 1)

Rank	Gender	R_0
1	Male	1.454
2	Female	1.424
3	Transgender	0.5110

Monthly Gender Average R_0
(Method 2)

Rank	Gender	R_0
1	Male	1.453
2	Female	1.423
3	Transgender	1.207

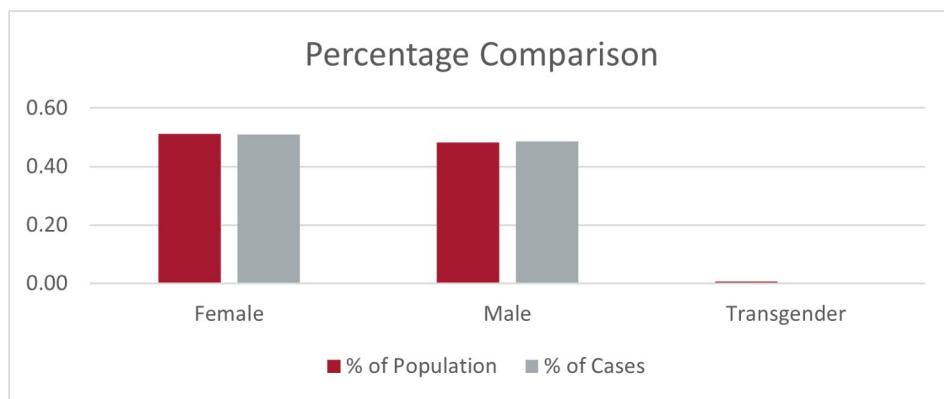

Seasonal Gender Average R_0
(Method 1)

Rank	Gender	R_0
1	Male	3.638
2	Female	3.565
3	Transgender	1.850

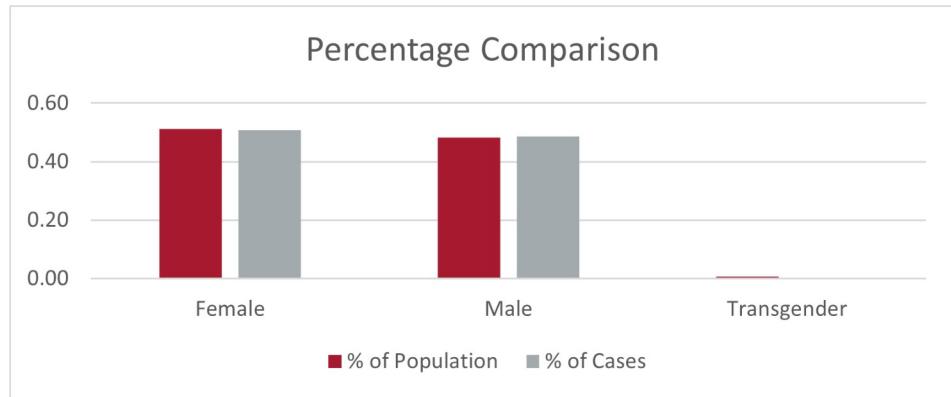

Seasonal Gender Average R_0
(Method 2)

Rank	Gender	R_0
1	Male	3.637
2	Female	3.566
3	Transgender	1.743

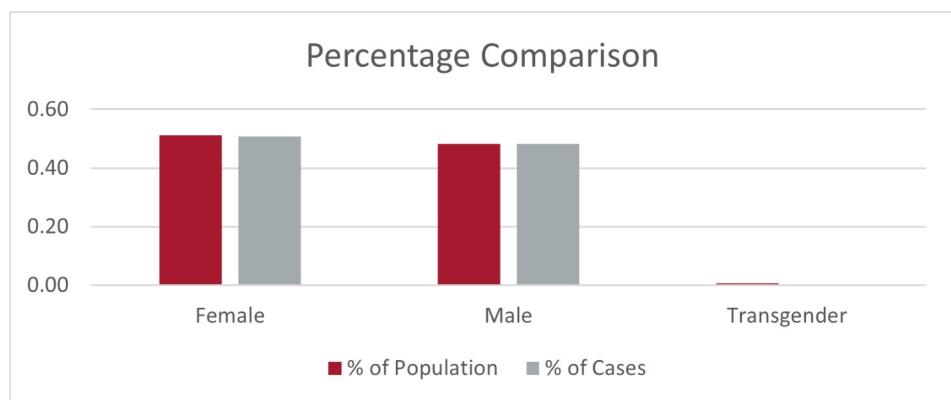

and the following charts:

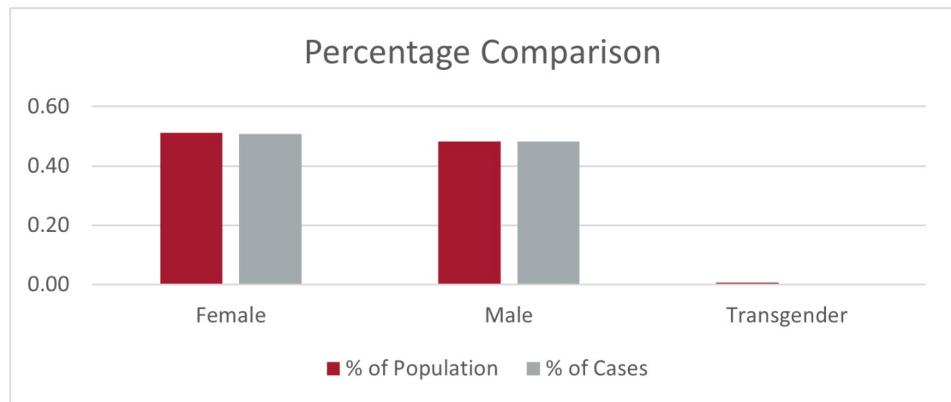

Biweekly Gender Percentage Comparison (Method 1)

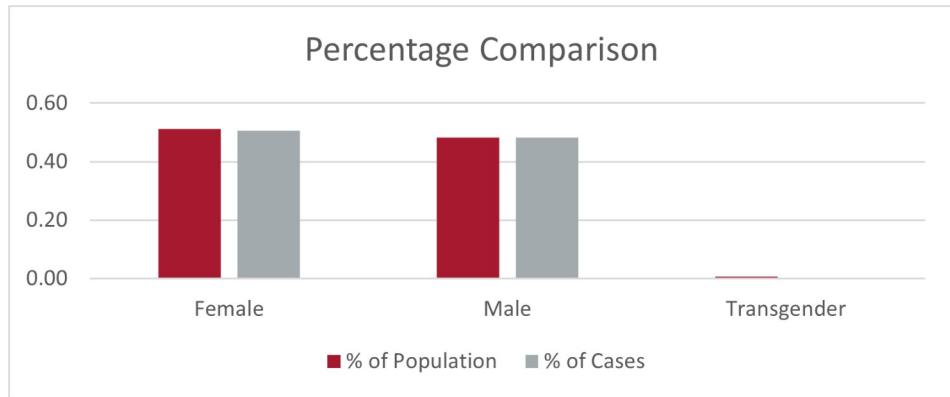

Biweekly Gender Percentage Comparison (Method 2)

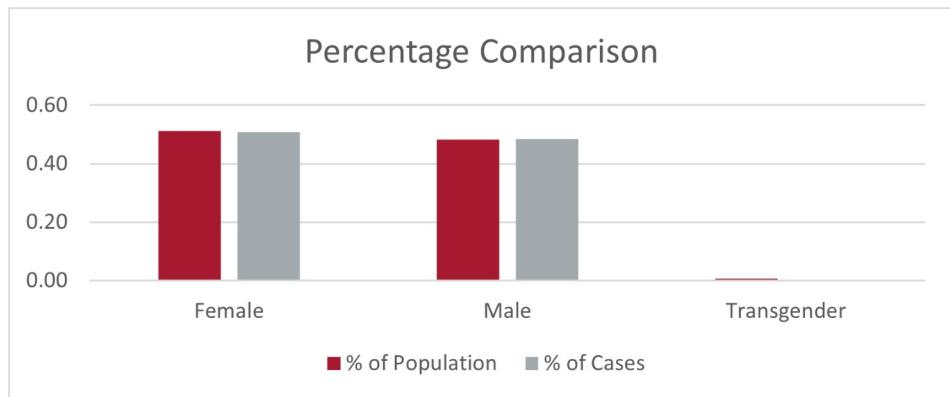

Monthly Gender Percentage Comparison (Method 2)

Biweekly Gender Percentage Comparison (Method 2)

Seasonal Gender Percentage Comparison (Method 1)

Seasonal Gender Percentage Comparison (Method 2)

This data is consistent in rank across all tables. This means that both males and females are almost equally at risk for CoViD-19 contagion. Analysis of the graphs verifies that any differences by gender are minimal, suggesting that both groups should be given equal attention. This data also suggests that Method 2, accounting for transgender cases before December 30th, 2020, more closely matches the actual cases, as it is not as volatile as Method 1, ignoring the possibility of transgender cases before reporting. This is likely a result of transgender people who are not out to their physician.

6.3 Race

The data on race is represented in the following tables:

Biweekly Race Average R_0

Rank	Race	R_0
1	White, non-Hispanic	1.274
2	Hispanic	1.106
3	Asian, non-Hispanic	1.087
4	Black or African American, non-Hispanic	1.041
5	American Indian/Alaskan Native, non-Hispanic	0.7741
6	Native Hawaiian/Pacific Islander, non-Hispanic	0.7601

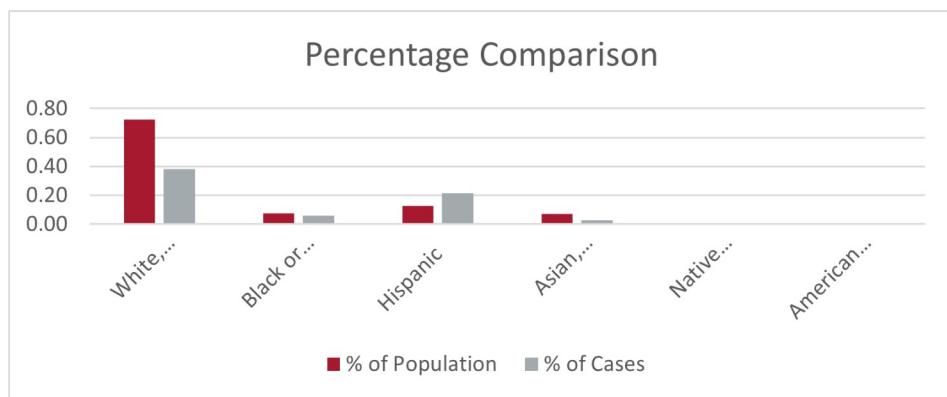

Monthly Race Average R_0

Rank	Race	R_0
1	White, non-Hispanic	1.221
2	Asian, non-Hispanic	1.196
3	Hispanic	1.188
4	Black or African American, non-Hispanic	1.112
5	American Indian/Alaskan Native, non-Hispanic	0.7534
6	Native Hawaiian/Pacific Islander, non-Hispanic	0.6571

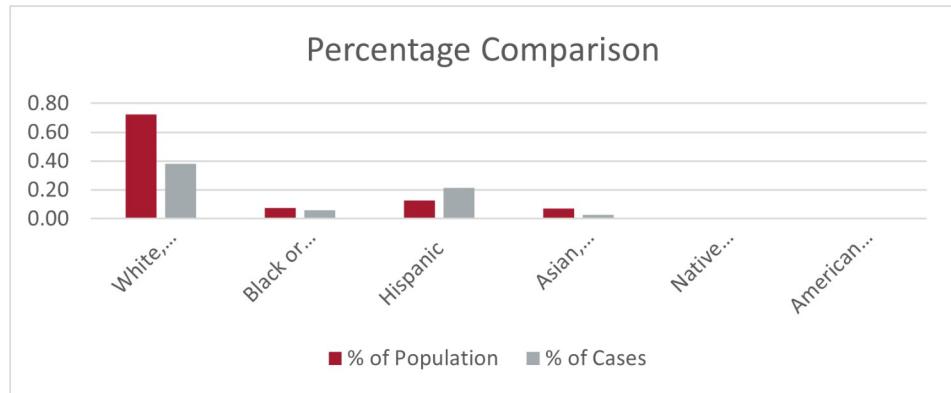

Seasonal Race Average R_0

Rank	Race	R_0
1	Asian, non-Hispanic	1.367
2	White, non-Hispanic	1.311
3	Hispanic	1.223
4	Black or African American, non-Hispanic	0.9245
5	Native Hawaiian/Pacific Islander, non-Hispanic	0.8594
6	American Indian/Alaskan Native, non-Hispanic	0.8513

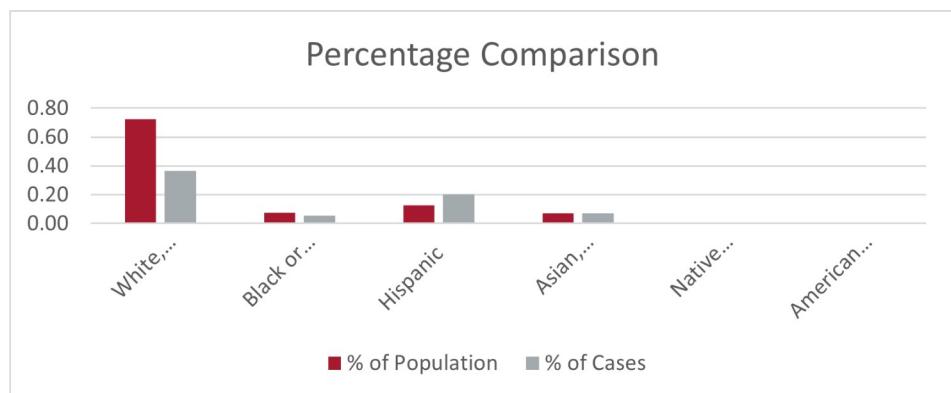

and the following charts:

Biweekly Race Percentage Comparison

Monthly Race Percentage Comparison

Seasonal Race Percentage Comparison

The data on race is significant. It is clear that the White, non-Hispanic community has the greatest CoViD-19 spread. However, the Hispanic community has the highest rate of infection, which is especially significant given the number of unknown race cases – more than thirty percent. Any campaigns to reduce the spread of CoViD-19 should focus on White non-Hispanics heavily, as they have a substantially greater rate of transfer. Alternatively, work to aid hard-hit communities should focus on Hispanic communities..

6.4 County

The data on counties is represented in the following tables:

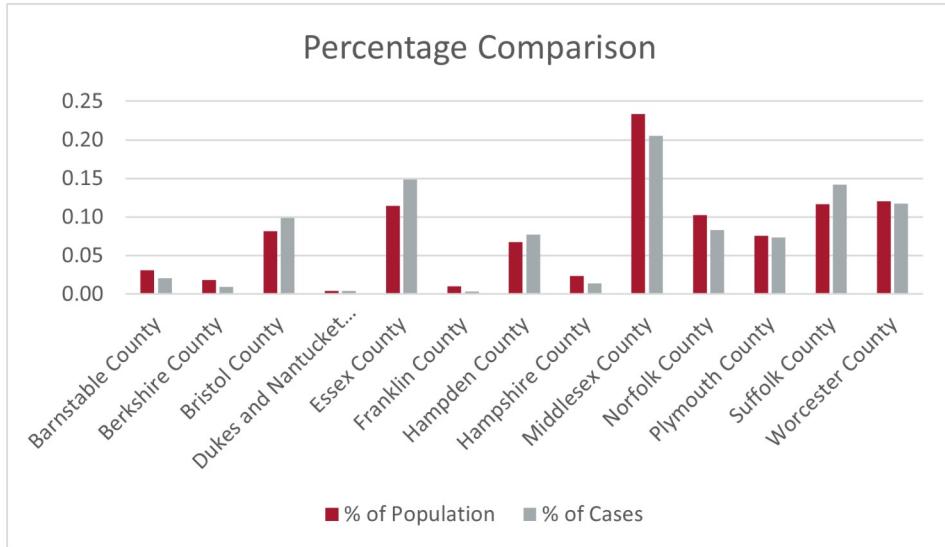

Biweekly County Average
 R_0

Rank	County	R_0
1	Dukes and Nantucket	1.220
2	Berkshire	1.198
3	Barnstable	1.070
4	Hampden	1.058
5	Suffolk	1.038
6	Bristol	1.036
7	Plymouth	1.024
8	Hampshire	1.010
9	Essex	1.002
10	Middlesex	0.9971
11	Norfolk	0.9868
12	Worcester	0.9835
13	Franklin	0.9442

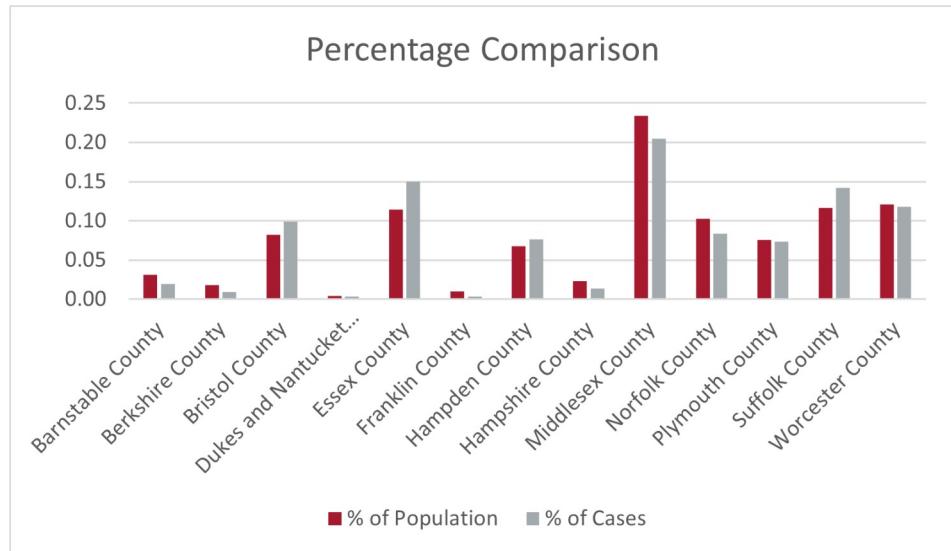

Monthly County Average R_0

Rank	County	R_0
1	Barnstable	1.344
2	Berkshire	1.338
3	Hampshire	1.139
4	Plymouth	1.093
5	Hampden	1.089
6	Dukes and Nantucket	1.088
7	Norfolk	1.072
8	Suffolk	1.069
9	Middlesex	1.039
10	Bristol	1.027
11	Worcester	0.9846
12	Essex	0.9628
13	Franklin	0.9370

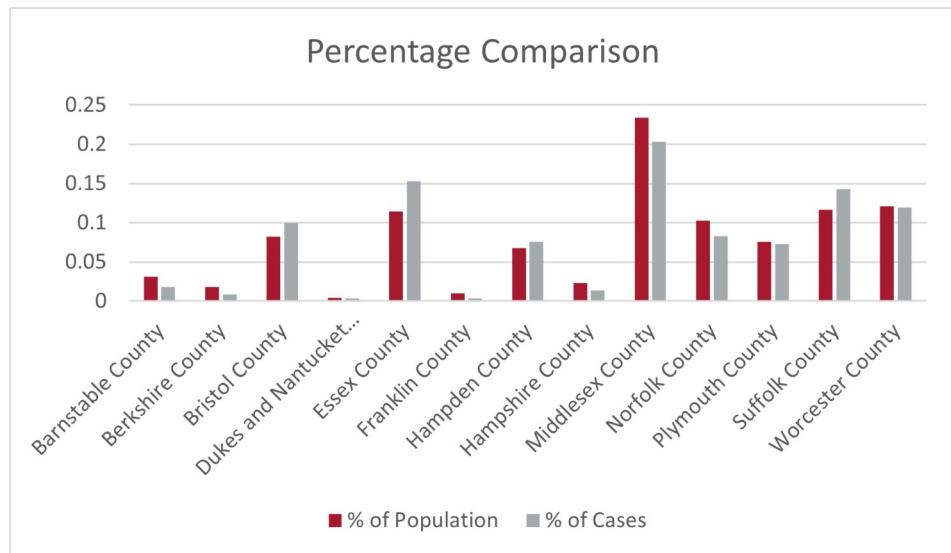

and the following charts:

Biweekly County Percentage Comparison

Monthly County Percentage Comparison

Seasonal County Percentage Comparison

The county data does not have a seasonal table as there is only one set of data, and a Basic Reproduction Number cannot be constructed without a slope. The existing data suggests a growing number of cases in Dukes County and Nantucket County, which likely follows from their existence as travel destinations. As the weather improves, cases will likely pick up in summer communities. Outside of Dukes and Nantucket, it is important to note that Barnstable County and Berkshire County are both consistently above the 75th percentile of R_0 values. Any work done would benefit from focusing in these four regions.

Work should also focus on Bristol, Essex, and Suffolk Counties. All have significantly higher rates of infection per capita than other regions, and thus require a disproportionate amount of resource dispatchment. Essex County especially requires attention due to the large ratio between cases and

population.

6.5 Higher Education

The data on higher education is represented in the following table:

Higher
Education Average
 R_0

Period	R_0
Biweekly	1.238
Monthly	1.363
Seasonal	2.892

The data for those pursuing a higher education suggests that they are roughly equal to the general population. This makes sense, as colleges are regularly tested. In doing so, they most accurately match the breakdown of the state - they compose a large percentage of tests. That being said, the fact that the biweekly average is above the state average is of concern and may require further examination..

7 Conclusion and Future Recommended Research Work

From the results, it is clear that many of the preconceived notions of who is most at risk for CoViD-19 are wrong. In many cases, it is the exact opposite of colloquial information holds when only considering infection. This data would likely change if death was accounted for, as a weighting of the severity of the virus would greatly impact the response to CoViD-19.

In many ways, this result should be expected. In communities where recovery is more certain, less precautions for safety have to be taken. If one feels that they are likely to survive because they are young, white, and live in an affluent community with ample health care, they can be more cavalier and take greater risks. These risks may still result in infection, but infection may not be a concern one feels it is likely that they will recover without a problem, and that if there is a problem, they will receive the health support that they require.

This maps across nearly every aspect of the tables. When age, race, gender, or county is examined, the greatest infection rates occur in the communities with the most robust medical knowledge, and with the most access to medicine. Well-off people with summer houses have access to better health care, and can take more risks compared to those in urban centers where many live at or below the poverty line. Most medical data is on men, with little to no information on transgender people. White, non-Hispanic

individuals similarly have the most focus in scientific literature. The elderly are more likely to die from any disease, and so have to be constantly vigilant against risks of contamination.

Additionally, people tend to interact within their communities. As a group suffers from a greater incidence of infection, it is more likely to continue to experience similar Basic Reproduction Number values. A prime example is nursing homes. In a situation where an incidence rate is high in a closed community, it will likely spread rapidly until there is no one left to infect. Similarly, without travel, cases would tend to stay localized to a county, city, and locality. Since many communities are homogeneous, this maintains racial separations, which are reflected in the data. This also suggests why the higher education population closely matched the general population in terms of the Basic Reproduction Number - college students are a heterogeneous mix of the various subgroups of the population, and as such, reflect the masses instead of any specific population.

This all works to suggest an inverse proportionality between case severity and case incidence in the population. This can be further supported or disproven by comparing incidence rate to death rate - if this hypothesis holds true, then the lower the incidence rate for a population, the greater the deaths in cases per capita ($DiCpC$). A weighting would have to be made for size of a population, and one such method would be to use the following formula:

$$DiCpC = \frac{D * R_0}{I}, \quad (28)$$

where $I = \text{infection}$ and $D = \text{deaths}$.

If this theory proves correct, then campaigns can be made to reduce CoViD-19 spread in communities with high R_0 values, and greater ambulatory care and health care services can be provided to the communities with high $DiCpC$ values.

However, the analysis of cases per capita through the graphs of percentage of population and percentage of cases suggests different results. It seems that cases started at a higher level in other communities, such as Hispanics, and Bristol, Essex, and Suffolk Counties. Although they do not have the highest rates of infection, they are the most disproportionately infected. Although efforts to contain the virus should focus on the high BRNs, but efforts to treat communities should focus on those with high cases per capita. To best analyze both the BRN and the cases per capita, the BRN might be multiplied by the percent of cases over the percent of the population.

Other studies could look at other communities. With more time and resources, the data can be used to calculate cities most at risk. With government cooperation, subcategories can be combined - instead of analyzing age, gender, race, and county separately, groups such as 0-19 year-old white, non-Hispanic women from Barnstable County can be compared to 80+ Hispanic men from Worcester County. This will provide greater specificity in which communities are truly at risk.

This study has provided an effective starting place for epidemiological research. Now, it can be utilized, and it can be expanded upon.

8 Appendices

8.1 Appendix A: Reference Tables

The following is the provided Data Documentation for the Massachusetts Data used.

For Cases (Report Date):

Date – Date to which this data applies – by the date the case was reported to the state

Positive Total – Running total of individuals that meet the confirmed COVID-19 case definition by the date the case was reported to the state

[Note that this will not equal the “Positive Total” column on the CasesByDate.xlsx file. This file is based on the date the case was reported and CasesByDate.xlsx is based on date the patient was tested.]

Positive New – New cases today that meet the confirmed COVID-19 case definition by the date the case was reported to the state (today’s positive total cases minus yesterday’s positive cases)

[Note that this will not equal the “Positive New” column on the CasesByDate.CSV file. This file is based on the date the case was reported and CasesByDate.CSV is based on date the patient was tested.]

For Age:

Date – Date to which this data applies

Age – Age categories covered by the data.

Cases_Last2Weeks – Total probable and confirmed COVID-19 case count for age group in the last two weeks

Start_Date – First day of the "last two weeks" period to which this data applies

End_Date – Last day of the "last two weeks" period to which this data applies

For Gender:

Date – Date to which this data applies

Sex – Sex category to which the data applies

Cases_Last2Weeks – Total probable and confirmed COVID-19 case count in the last two weeks

Start_Date – First day of the "last two weeks" period to which this data applies

End_Date – Last day of the "last two weeks" period to which this data applies

For Race:

Date – Date to which this data applies

Race/Ethnicity – The Race/Ethnicity category to which the counts apply

All Cases – Total number of probable and confirmed COVID-19 cases by race/ethnicity

For County and State:

County – Name of the county in MA to which this data applies; Address information for these cases listed in "Unknown" are currently being obtained.

Total Case Count – Total number of confirmed COVID-19 cases since Jan 1, 2020

Case Count (Last 14 Days) – Total number of confirmed COVID-19 cases in the last 14 days

For Higher Education:

Date – Date to which this data applies

New Higher ED Confirmed Cases – Confirmed COVID-19 cases that are associated with higher education testing that on that date received a positive molecular test

Total Higher ED Confirmed Cases – Running total of confirmed COVID-19 cases that are associated with higher education testing

8.6 Appendix F: Monthly by Date

These tables were constructed using the data from Massachusetts Reference Data – Cases (Report Date), Massachusetts Reference Data – Age, Massachusetts Reference Data – Gender, Massachusetts Reference Data – Race, Massachusetts Reference Data – County and State, and Massachusetts Reference Data – Higher Education. LS2C stands for Lifestyle Social Contract. BRN stands for Basic Reproduction Number.

8.7 Appendix G: Seasonal by Date

These tables were constructed using the data from Massachusetts Reference Data – Cases (Report Date), Massachusetts Reference Data – Age, Massachusetts Reference Data – Gender, Massachusetts Reference Data – Race, Massachusetts Reference Data – County and State, and Massachusetts Reference Data – Higher Education. LS2C stands for Lifestyle Social Contract. BRN stands for Basic Reproduction Number.
